Smart Face Masks for Covid-19 Pandemic Management: A Concise Review of Emerging Architectures, Challenges and Future Research Directions

Temitayo M. Fagbola, *Member, IEEE*, Funmilola I. Fagbola, Oluwasegun J. Aroba, Ruchi Doshi, *Sr. Member*, IEEE, Kamal Kant Hiran, *Sr. Member*, IEEE, Surendra Colin Thakur

***Abstract*—Smart sensing technology has been playing tremendous roles in digital healthcare management over time with great impacts. Lately, smart sensing has awoken the world by the advent of Smart Face Masks (SFM) in the global fight against the deadly Coronavirus (Covid-19) pandemic. In turn, a number of research studies on innovative SFM architectures and designs are emerging. However, there is currently no study that has systematically been conducted to identify and comparatively analyze the emerging architectures and designs of SFMs, their contributions, socio-technological implications, and current challenges. In this paper, we investigate the emerging SFMs in response to Covid-19 pandemic and provide a concise review of their key features and characteristics, design, smart technologies, and architectures. We also highlight and discuss the socio-technological opportunities posed by the use of SFMs and finally present directions for future research. Our findings reveal four key features that can be used to evaluate SFMs to include reusability, self-power generation ability, energy awareness and aerosol filtration efficiency. We discover that SFM has potential for effective use in human tracking, contact tracing, disease detection and diagnosis or in monitoring asymptotic populations in future pandemics. Some SFMs have also been carefully designed to provide comfort and safety when used by patients with other respiratory diseases or comorbidities. However, some identified challenges include standards and quality control, ethical, security and privacy concerns.**

***Index Terms* — Aerosol, Coronavirus, Covid-19, Mask Technology, Material Science, Nanotechnology, Pandemic Management, Smart Face Mask, Smart Sensing.**

I. Introduction

CORONAVIRUS is a deadly infectious disease of huge public health concern globally. It has accounted for over 442 million infected cases and over 5.98 million deaths around the globe since the year 2020 when it emerged[1]. Among several strategic control measures applied by the World Health Organization (WHO) and the governments of the world in the fight against this ravaging pandemic is the introduction of face masks [1]–[4]. Face mask (FM) can be described as a form of protective fabric of the face which when worn correctly, may safeguard the wearer from direct exposure to the virus [4]. Use of FM, as a means for public health outbreak management, has been reported to have reduced the burden of Covid-19 attacks and associated mortality cases greatly [5].

However, the traditional FM is highly prone to retaining infected aerosols or loads of viral antigen on its vulnerable surface [6], [7] which may pose huge infection or re-infection risks to the wearer. This may likewise lead to increased public spread of the virus if the FM is not hygienically used or not properly disposed after use. Although Gómez-Ochoa and Muka (2020) reported that using a FM in a community has no effect in curtailing the spread of Covid-19; however, emerging evidence from some recent country-wide evaluation studies have revealed that the proper use of FMs can assist greatly in mitigating the risk of contracting Covid-19 disease or its spread [6], [8], [9]. Generally, some health-related risks and socio-cultural challenges associated with the use of FM have limited its wide adoption and the compliance level of its use by the public [10]. Such risks, which may be heightened by the use of FM, have been identified to include air flow obstructions in its different forms [4] which can lead to suffocation or prolonged breath seizure in patients suffering from lung problems, severe obstructive pulmonary diseases or any other respiratory diseases [1], [2] and eventually cause death. Other social-

related challenges associated with the use of FMs include cultural misunderstandings, stigmatization [8], [11], limited social interactions and communications [2], [5], quality and cost issues [3], [11]. This set of risks and challenges may have overridden the actual purpose and effectiveness of most face masks.

Lately, the world has witnessed accelerated development and innovative use of digital technologies in the fight against disease pandemics [10], [12]. The Covid-19 pandemic has equally provided evidence that the future of public health is tending towards integrated digital innovations. In Figure 1, a conceptual summary of several disparate digital technologies, social computing and data processing approaches that have played prominent roles in enabling easy and effective management of the global Covid-19 pandemic is presented [13]. Such techno-driven systems and approaches include but are not limited to GPS-enabled drones for screening, surveillance, disinfection and delivery of medical supplies, computer vision, automated contact tracing apps, security and privacy-preserving technologies, telemedicine, disease detection wearables and sensors, live casualties reporting apps and user-support mobile applications among others [12], [14], [15].

Fig. 1. Digital Technologies Applications in Public Health for Pandemic Management [12]

In an attempt to address the challenges of the traditional FMs, the wearables and smart sensing domain have amazingly awakened the world with the evolution of smart face masks (SFM). SFM is a product of an integration of smart sensors and the traditional face masks thereby translating the latter to a multifunctional wearable healthcare device. Though the development of SFMs is at its infant stage; however, a number of promising solutions are currently emerging [16]–[19]. Some SFMs are now capable of providing early warnings and alerts of electronically or remotely sensed diseases in the body of the wearer for immediate care [20].

Most importantly, in preparation for the next-generation innovative smart face mask solutions, it is imperative to investigate the state-of-the-art face mask designs and architectures, their specifications, features and their limitations. This attempt will further help to gain insights into the social and technological challenges of the development and use of SFMs as well as identify new areas for future research. However, no previous study has been conducted in this direction. In this paper, we provide a concise systematic review of the features, architecture and design, opportunities, challenges, and future research directions for the emerging smart face masks. In turn, five (5) research questions have been identified, investigated, and analyzed as presented in Table 1.

TABLE I

THE RESEARCH QUESTIONS (RQ) FOR SMART FACE MASKS DESIGN & USE

Research Question	**Motivation**
RQ1: What features do the smart face masks possess to more effectively reduce the risk of contracting Coronavirus or support ease of use among some people in defined health risk groups like those with respiratory or pulmonary problems?	This information will help to identify the key characteristic features of smart face masks that are evident and which can be used to comparatively evaluate them. With this information, it becomes possible to determine how flexible, scalable, effective, and efficient each emerging smart face mask is.
RQ2: What are the different architectural designs and/or smart technologies that have functionally-aided the emerging smart face masks? What areas of the current smart face masks technology can be scaled up or extended to increase the capabilities of SFM beyond the state-of-the-art applications?	The purpose is to highlight the disparate innovations and smart technological advancements surrounding the architectural design of smart face masks. These set of SFM information can be further studied for extensibility, scalability, efficiency, and general improvement purposes.
RQ3: What extensions of smart face masks exist beyond being a protective covering only?	The purpose is to identify other public health applications and capabilities of the emerging state-of-the-art smart face masks beyond their use as protective covering. What technologies and models among other approaches have been adopted or developed to initiate the design of smart face masks? This knowledge can help researchers and smart face mask engineers to be in tandem with current SFM trends and identify other possible extensions beyond the current technological solutions and design mechanisms of smart face masks.
RQ4: What are the challenges and notional public concerns regarding their readiness to adopt or use smart face masks?	The purpose is to identify the reactions of the end-users of smart face mask solutions and know if there exists any concern arising or that may arise relating to the use. This information can assist the public health service providers, regulators, and the government to devise sustainable and strategic approaches to increase the readiness, acceptability and adoption of smart face masks to gain high compliance use of the smart face masks towards effective pandemic disease transmission and control.
RQ5: What future research can emanate from the current SFM technology to extend its contributions towards pandemic management in the future?	This information will assist to identify areas of the emerging smart face mask designs that require further investigation to be more effective as a protective covering or beyond. It will also assist to bring together multidisciplinary researchers that may be interested in improving or extending the emerging state-of-the-art smart face mask solutions from a number of perspectives.

Main contributions of this paper are as follows:

- This research discovers that smart sensing has inspired the current innovations in face mask design in the COVID19 era by introducing new features and capabilities which are location-aware technologies and flexible architectures, energy conservation and awareness, self-power generation potential, aerosol filtration efficiency, safety awareness, reusability and cost-effectiveness. These newly integrated features can help to gain deeper insight into understanding and evaluating the quality, user acceptability, government policies and socio-economic relevance of the emerging smart face masks. This is in response to RQ1 (*see section III B*).
- The traditional face mask is limited in its sole function as a protective covering. This research finds that a number of emerging architectural designs and/or smart technologies have functionally aided and extended the capabilities of face masks beyond just being a protective covering by making it smart. Most of the emerging architectures and smart technologies employed are based on ultrathin Au/parylene/Teflon AF films pressure sensors, NRF2832 SoC board with a chip antenna on the BMD-350 BLE Module, Copper3D technology and Ultimaker Cura, STM32L4R5AI ARM-M4 Ultra Low Power microcontroller, laser scattering-based Sensirion SPS30, polydimethylsiloxane board, triboelectric filters, polytetrafluoroethylene and Electrospun Polyetherimide among others. In turn, the capabilities of SFMs have become extended to include but not limited to the automatic detection of microbes and aerosols, wireless CO2 monitoring, remote health-metrics sensing and monitoring, disease screening and diagnosis, air quality sensing, mask usage time sensing, mask fitness sensing, head and body motion sensing. These extended capabilities have eliminated the challenges of the traditional face masks. This is in response to RQ2 (*see sections IV A, B*) and RQ3 (*see section VA*). We further identify the challenges and notional public concerns regarding their readiness to adopt and use smart face masks. This is in response to RQ4 as discussed in section VB.
- From our findings, the emerging smart face masks have potential to provide opportunities for researchers, network engineers and data engineers to collect data from SFMs in the edge and/or their network. As a potential edge device in a connected mask network scenario, SFMs would be able to rapidly collect, aggregate and process data. This data can be used to more efficiently derive relevant insights that can aid better use and effective societal impact. In this direction, we have presented a number of research gaps that can leverage such data for key technological, security and societal insights. We have also provided suggestions on possible extensions and scalability options in SFMs in a bid to increase their capabilities with wider public acceptance gain. This is in response to RQ5 (*see section VC*).

The rest of the sections are as follows: in section II, review of related works on smart sensing in pandemic and healthcare management is presented; section III presents the method; section IV presents the review of literatures on the characteristics, design methods, technologies, and architectures of some emerging smart face masks towards Covid-19 pandemic management. In section V, direction for future research is presented while section VI concludes the paper by summarizing its key contributions.

II. RELATED WORK

The role of smart sensing in healthcare disease management cannot be over emphasized. In this era of Covid-19 pandemic, a number of studies are being carried out to report several innovative smart applications or the use of smart sensing technology in pandemic disease management. Regarding works that establish strong connections between humans and the use of technology in critical events, [5] performed a comparative study of governments' perspective to the use of technology in Covid-19 management in some settings. The author investigated technology-based and human-based approaches that dominate China and the western democracies, respectively as case studies. The study mentioned that a tech-driven approach may be more effective in fighting Covid-19. While this is a welcoming development, tech-driven Covid-19 management may pose some privacy concerns to the public [14]. In another study, [21] reviewed existing smart innovations (mainly sensor technology, mask, robotics, drone, artificial intelligence) and their associated frameworks that have recently emerged to tackle the global emergence of the Covid-19 pandemic [22]. The authors identified the disparate smart devices and smartphone applications used in a number of geographical distributions to manage Covid-19 pandemic. The societal changes and health intervention impacts that these smart technologies have brought to limelight in counter response to emergency situations are also presented.

In an attempt to understand capabilities of wearable technologies including face masks, Ivanoska-Dacikj & Stachewicz (2020) performed a systematic review and critical analysis of the capabilities offered by the use of wearable technologies and smart textiles in the face of the Covid-19 pandemics via a comparative study of the roles of face masks in the management of past and present pandemics. In the work of [23], several raw materials and testing approaches that have been used in the production of face masks were reported. The authors also reviewed the varying perspectives of the public and sustainability concerns regarding the production and wearing of face masks. Dalia and Khaled (2021) conducted a review of the properties of advanced materials being used for the manufacturing of medical coverings and wearable health care devices. They reported the role of design in textile rendering and associated challenges with smart wearable device technologies and applications. In another study conducted by Farzaneh and Shirinbayan [24], the authors presented a review of the production process and quality control approaches for the traditional face masks. Further, they argued the need for thorough quality assurance tests, including dynamic respiratory resistance, to ascertain that the masks being produced meet minimum acceptable quality specifications. As evident, none of these existing works has considered a systematic review around the emerging SFM architectures, the socio-economic and technical opportunities they may present, their potential challenges and future research opportunities. As a result, this study presents a concise review of the emerging architectures of SFMs for use in Covid-19 pandemic management, the opportunities they present, the associated challenges and concludes by suggesting areas for potential future research.

III. METHOD

In this section, we highlight the method used for the selection of articles and the analysis conducted in this study.

A. Data Selection

For the purpose of the review that was conducted in this study, the "search" tool of the Scopus database engine was used to fetch and obtain articles relating to smart face masks and Covid-19 pandemic. Scopus database was considered because it accommodates large article base with over 4600 health science titles, and having a hundred percent MEDLINE, EMBASE and Compendex coverage which are most relevant to this study [25]. An advanced search was conducted on the 2nd February 2022 using search key phrases like "Smart Mask" OR "Smart Face Mask" OR "Bio-sensor Face Mask" OR "Face centric biosensing" OR "Digitized Mask" AND "Covid-19" OR "Coronavirus". The search produced a total of 59 articles from which 12 articles were excluded. The exclusion criteria of articles for this study include the scope of an article if it is outside of SFMs technology or if it is a book. 15 duplicate articles were found and removed. In all, 32 articles were found very relevant to the current study and analyzed. However, some relevant articles within our inclusion criteria from major newspaper companies that mentioned "smart mask" OR "Smart face mask" in their headlines were also reviewed.

B. Data Analysis

We analyzed the literature and identified key features of most emerging smart face masks which can be used for their evaluation. These include technologies and architectures, energy conservation and awareness, self-power generation potential, aerosol filtration efficiency, safety, reusability and cost. These features will help to gain deeper insight into understanding and evaluating the emerging smart face masks. The basic findings are presented in section IV of this paper. This attempt will also assist to better understand the social relevance and implications surrounding the development of SFM as well as the key drivers for its anticipated public acceptance. For clarity purposes, some key features mentioned above are contextually defined as follows:

1) *Smart Face Mask Architecture:*
The architecture refers to the structural make-up and design specifications of a SFM and the associated hardware. For instance, this definition attempts to determine the components of a SFM and its design approach.

2) *Smart Face Mask Technology:*
This explains the smart technological innovations, processes, systems, procedures, or approaches that have been integrated into the structural architecture of a face mask. This may account for the level of efficiency or effectiveness of some features like self-power generation capability and energy conservation.

3) *Energy-awareness:*
This explains whether a SFM is able to efficiently and effectively sustain and conserve device energy over a sufficient period of time.

4) *Self-power generation capability:*
This indicates the energy options available to power up a SFM. We discovered that the majority of the SFMs leverage on battery, which is the size of a small coin, to power the face mask and so unable to self-generate a power of their own. However, few emerging SFMs have shown potential to harvest energy (both in kinetic and thermal form) from the sun and wearer's breathing activities to power themselves.

IV. SMART FACE MASKS IN COVID19 PANDEMIC MANAGEMENT

In this section, the design methods, technologies and architectures of the emerging SFMs are presented.

A. Smart Face Masks

The smart mask design technology has brought together many researchers from the field of engineering, nanotechnology, material science, aerosol science, surface science and the public health domain to improve SFM's role in effectively curtailing disease spread and in extending its functionalities beyond being a protective covering alone. Smart face mask, otherwise known as bio-sensing face mask, which has played significant roles in curtailing the spread of Covid-19 disease, is commonly an easy to use, multilayered (microfiber, nanofiber, and microfiber) personal protective equipment most often made from non-woven fabric [2], [26], [27]. In Fig. 2, the visual look of the different types of face masks are presented. Type 2(a) is woven (meaning that fabric threads are interlaced) while others are non-woven.

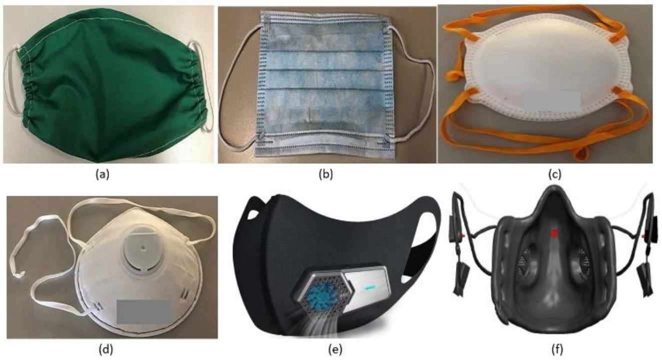

Fig. 2. (a) A Home Made Face Mask [2]
(b) A Typical Surgical Face Mask [2]
(c) Filtering Face Piece Mask [2]
(d) Filtering Face Piece Mask with a valve gadget [2]
(e) A Reusable Smart Air Face Mask[2]
(f) 3D AG-47 SmartMask (Fois et al., 2021)

1) *Characteristics of Smart face Masks*
Smart face masks are protective coverings, and like every other nano-biosensor-based device, are characterized by the ability to acquire and monitor body vital signs via multiple sensors. Such vital recordings which may include but not limited to cardiorespiratory signals, body temperature, blood pressure, steps taken per day, body motion, sleep duration, hydration level and respiratory rate (Ivanoska-Dacikj & Stachewicz, 2020) can be used for non-invasive detection of Covid-19 viral antigens [9] and other diseases in the body. In addition, some SFMs use saliva samples collected on face masks to detect

---

[2] https://tinyurl.com/9sbu8jpy

diseases [7]. Texturally, SFMs are usually air-permeable, flexible, hydrophobic, strong, extensible and can exist in different cross-sectional shapes, fineness, fiber length and level of absorbency [27], [28]. A typical non-woven fabric is often made from any of a polyester, polypropylene, polycarbonate, or a polystyrene [20].

B. Smart Face Masks Design, Technologies and Architectures

In this section, design methods, technologies and architectures of some emerging smart face masks are discussed. In order to monitor the breathing conditions of people in real time in a pandemic situation, [29] designed a self-powered SFM from two ultrathin Au/parylene/Teflon AF films pressure sensors with a thickness of ≈5.5 (m) and a weight of ≈4.5 mg. Its corona charging is fitted with a Dongwen DW-N503-4ACD2 or DW-P503-4ACD2 power source, a ground electrode and a corona needle. The SFM possesses high electrostatic induction efficiency and is readily sensitive to breathing airflow; however, it is non air permeable. In the work of [17] Zhu et al., application of harmonic sensors in the remote sensing of liquid levels, mechanical cracks, vital signs, humidity and so on was extended to cough detection and monitoring in Covid-19 situations. The authors proposes a wireless SFM based on a lightweight harmonic sensor with capability for continuous and rapid monitoring of cough associated with Covid-19. The smart mask design is built on a passive harmonic tag with a lumped element-based frequency multiplier, a meander-line antenna operating at 1.5 GHz for generating interrogation signals to the wearer and an inverted-F antenna operating at 3.0 GHz and generates time-series information from which the frequency and pattern values of the cough are obtained.

Fig. 3. A sample Architecture of a SFM with CO2 monitoring capability (a) its NFC sensing tag (b) its CO2 sensing layer (c) its smartphone application for support [30]

In another study, [30] Escobedo et al. developed a smart face mask that uses an opto-chemical sensor and Hydroxypropyl methylcellulose polymer to effectively monitor possible hyper re-inhaling of gaseous CO2. This is to allow for a smart approach to managing the adverse effect and discomfort of a prolonged use of a face mask by wearers. The architecture of the SFM is made up of three components which include a near-field sensing tag, a CO2 concentration sensing layer and a smartphone-based front-end application as presented in Fig 3. The low-power near-field sensing tag is microcontroller-enabled and allows for processing and control of the SFM's data. In addition, the CO2 sensing layer allows for an automatic detection and measurement of the gaseous CO2 concentration on the face mask while the smartphone application layer offers end-users' visualization support and control of parameters of interest including the real-time display of the level of concentration of gaseous CO2 on the face mask.

Jarkko et al.[14] (2022 introduced a smart 3D-printed face mask made with a FlexFill 98A filament that is made from thermoplastic polyurethane. Although it is comfortable to wear, it is difficult to establish that the smart mask is energy efficient and weight friendly owing to its need for an alternative power plan which may pose weight burden on the wearers. In another related study, an open-source smart face mask tagged "Facebit" is developed by [31]. Facebit uses contactless ballistocardiography to monitor heart rates from head's micro movements also with inbuilt capabilities to detect mask degradation and improper fit. Its hardware is built from NRF2832 SoC board with a chip antenna on the BMD-350 BLE Module. The three sensors on the board include the Si7051 temperature sensor, the LSM6DSL 6-DOF Inertial Measurement Unit and the LPS22HB barometer. Facebit is capable of harvesting energy from sunlight via a flexible PowerFilm MP3-37 4.49X1.44in 150mW solar panel and from head movements using "shaker", a fabricated lightweight harvester. Kinetic force in breath is also converted into electrical energy using a triboelectric nanogenerator. The energy requirement of the Facebit wearable is also complemented with a tiny, 105 mWh primary cell battery.

[32] Gravina developed a smart mask based on an improved Copper3D technology and Ultimaker Cura. The mask, embedded with temperature, accelerometer, humidity, and light sensors, is powered up with a lithium battery and has smartphone application support. The authors also adopted support vector machine and Naïve Bayes algorithms to detect when a mask is worn and if it is properly worn. In the work of [26] Fois, an anti-Covid-19, active-passive filtering device, tagged "AG47-SmartMask" is proposed. The AG47-SmartMask is embedded with sensors that continuously monitor the cardio-pulmonary activities of the wearer, including the heart rate and the body temperature for early detection of Covid-19 especially in asymptotic sufferers. AG47-SmartMask uses an ARM 32-bit Cortex-M4 CPU and a STM32L4R5AI ARM-M4 Ultra Low Power microcontroller unit in its design. The filter is non-disposable as it can be used for a minimum of 60 days at a stretch. Lazaro et al. [33] developed an integrated dual heat flux sensor characterized with a FFP2 mask with capabilities to detect cough events and remote healthcare monitoring including breathing and temperature. However, its power generation is based on an AtTiny402 microcontroller powered by a 500 mAh lithium polymer (LiPo) battery.

In another work, Fischer et al. [16] developed "Masquare", a smart face covering that incorporates sensing electronics with layered textile and 3D printed structures. It uses dual differential barometers (BME680 and LPS22HB) which equally act as a spirometer to measure transient airflow and respiratory pressure. To enhance users' experience and minimize cost, a low-cost and customizable smart face mask was developed by Kim et al. [34] to monitor a wearer's face strain and temperature. The design approach of the SFM is based on wireless aerosol jet printing technology and a cloud-based data backup technique. The approach follows a three-dimensional face scanning of the user for geometry information, strain gauge sensor design and aerosol jet printing, customized sensor placement on a mask and real-time transmission of sensor data to the cloud. In a similar manner, a low-cost closed-loop smart face mask was developed by Kalavakonda et al. [20]. The SFM design is based on an active mist generator with a piezoelectric transducer operating at 110 kHz and two laser scattering based Sensirion SPS30 particulate matter sensors. Further, it presents the wearers with a mobile application support interface to monitor battery levels and conduct surrounding air quality checks.

A "body to device to cloud" model-based SFM tagged "Lab-On-Mask (LOM)" was proposed by Pan et al. [35]. The non-contact LOM design is composed of data processing modules, signal processing sensors and the Bluetooth data output. It uses a polydimethylsiloxane board to embed the monitoring sensors for blood pressure, heart rate and the blood oxygen saturation. Regarding self-powered smart face masks, Ghatak et al. [27] proposed a low-cost multilayer self-powered smart mask (MSSM) made from tribo-series material. It is self-customizable to provide maximum comfortable texture and safety when in use. The MSSM has an inner, middle and smart layer. The inner and the middle layers are triboelectric filters solely for filtering Covid-19 virus. The smart layer becomes self-activated automatically through the vocal activities of the wearer. The MSSM thermal power generation strategy originates from static and triboelectricity and up to 0.4W per second which is capable of electrocuting incoming virus-invaded aerosols due to its high aerosol infiltration efficiency. In the work of Masna et al. [20], a closed-loop control system was used to sense and determine ambient air quality. This also involves the activation of a piezoelectric actuator, which has the capacity to generate a mist spray to load and spray surrounding airbornes.

Liu [36] used nylon fabrics, polytetrafluoroethylene and a linear motor-based triboelectric filtering approach to develop a self-powered washable face mask with electrostatic adsorption capability. In another attempt, Cheng et al. [23] developed a sandwich-structured electret nanogenerator with Electrospun Polyetherimide (PEI) nonwoven-based SFM. The SFM serves dual purpose of dynamically removing particulate aerosols and generate electricity as well as monitor respiratory rates. The high energy efficiency of the SFM makes it possible for it to be used continuously for an average period of 40 hours. The experimental process in the production is based on orderly steps including the PEI nonwoven, corona charging basically to inject charges into the PEI nonwoven, sandwich-structured nano-generator assemblage of 5x5 〖cm〗 ^2 and characterization. However, the PEI-based SFM has not been widely adopted for commercial use as it is still subject to further validation and testing. In Table 2, some emerging smart face masks, their associated features and functional contributions are presented.

TABLE II
SOME EMERGING SMART FACE MASKS, THEIR ASSOCIATED FEATURES AND FUNCTIONAL CONTRIBUTIONS

#	Authors	Design Method / Concept	Re-Usability	Energy-awareness	Self-Power Generation	Aerosol Filtration Efficiency	Functional Contribution
1	[29] Zhong et al. (2022)	self-powered SFM from two ultrathin Au/parylene/Teflon AF films pressure sensors with a thickness of ≈5.5 (m) and a weight of ≈4.5 mg	Yes	Yes	Yes. 	(2020)	protection					However, it has not been widely adopted for commercial use and may still be subjected to further validation and testing before full deployment and commercialization.
15	[36] Liu (2018)	SFM based on polytetrafluoroethylene and a linear motor-based triboelectric filtering approach	Yes	Yes	Yes	High	SFM with electrostatic adsorption capability. It has not been widely adopted for commercial use and may still be subjected to further validation and testing.
16	[39] Cheng et al., (2017)	Sandwich-structured electret nanogenerator with Electrospun Polyetherimide (PEI) nonwoven	Yes	Yes. It can conserve energy and used continuously for an avg. period of 40 hours	Yes.	High	SFM is able to dynamically remove particulate aerosols. It has the ability to remotely monitor respiratory rates of humans.

V. OPPORTUNITIES, CHALLENGES AND FUTURE RESEARCH DIRECTIONS IN SMART FACE MASK TECHNOLOGY

In this section, we discuss the opportunities, challenges and future research direction for the development and use of smart face mask technology especially in the management of Covid-19 pandemic.

A. Opportunities

Asides offering possible low cost and off-the-shelf rapid protective response in emergency pandemic outbreak, SFMs also have potentials to act as a pervasive means of making calls and sending text messages[3]. The emergence and use of SFMs, owing to their ubiquitous and sensing abilities, may indicate the first step in the automatic collection, storage and analysis of health data emanating from body vita signs, body fluid composition, temperature readings, heart readings, breath and remote spatio-temporal health information and so on (Masna et al., 2020). This development may birth the building of dedicated servers and data centers for SFMs. In the academia and industry, data engineers and scientists can use data obtained from SFM to generate key insights that can contribute to more social good. For example, predictive monitoring of vital signs and disease progression. In addition, beyond curtailing the spread of COVID19 pandemic with the use of SFM, it can also be adapted to managing other air-borne communicable diseases. Other potential areas of application of SFM may involve non-invasive and real-time monitoring of human body physiological vita signs towards early disease detection and management [16]. It may be used as an air purifier, odour data acquisition tool for potential early automated detection of oral squamous cell carcinoma and other oral cavity cancers. Furthermore, since SFM has potential to acquire personal health metrics, data acquired may help in building user-aware and personalized health information recommendation systems for wearers. Furthermore, SFMs can help to reduce the environmental toll, health hazard and cost challenges associated with the disposable face masks. From the socio-economic point of view, post legislative approval of the wide deployment and use of SFMs across many nations globally shall be a great opportunity for the global economy to grow. Technically, it may also facilitate capacity building, empowerment opportunities and tech job creation for young entrepreneurs, technocrats, local and international tech markets and businesses, and may also lead to rise of local manufacturers of SFMs. Internationally, SFM technology may be greatly beneficial to boosting bilateral trade agreements and economy growth among different nations of the world with respect to commercialization and import/export relations around SFM raw materials, which in turn, may translate into increased gross domestic product and reduced recession globally.

B. Key Concerns and Challenges

The key concerns and challenges regarding the development and use of SFM discussed in this section include government policy and public surveillance, safety, security and privacy issues and specification and standards issues.

1) *Government policy, Regulations and Public Surveillance:* Are there existing government policies that governs the development and use of SFM and its data? Are there approved minimum regulatory standards and specifications for the design of SFMs and other techno-driven health care devices as well as use of health data collected? For example, before the emergence of COVID19, the production, distribution, and use of cloth face coverings like the surgical masks are cleared and regulated by the Food and Drug Administration (FDA) in the United States of America. FDA is a governmental agency that is saddled with the responsibility to ensure that public health is protected. An agency in the United Kingdom saddled with a similar responsibility is the Medicines and Healthcare products Regulatory Agency (MHRA). However, since the emergence of COVID19, a major concern is that it is largely unknown how well democratic government policies around the world has embraced technology-driven approaches to respond to the fight against communicable diseases, and most especially COVID19. The sensing nature of SFM makes it a potential tool for human monitoring [40] and identification[4]. This raises concern of

[4] https://news.northwestern.edu/stories/2022/01/fitbit-for-the-face-can-turn-any-face-mask-into-smart-monitoring-device/

possible active surveillance and censoring of the public and their opinions by the government [5]. Since surveillance potentials of the SFM poses high risk to human rights, in turn, it may frustrate and jeopardize public acceptance of its use [12]. If no regulation is in place, abuse of use is inevitable.

2) *Safety, Ethical, Security and Privacy Issues:*

It is important to establish security measures and privacy control, perhaps by enacting certain governmental policy, which can address potential abusive use of SFM technology and data. This is to ensure that the safety and privacy of the wearers of SFMs are not breached or intentionally locked-in. For example, a breach in health data privacy may lead to discrimination of the owner [14]. The procedures governing the acquisition, storage and use of data sourced from SFMs must be well regulated to avoid unethical violations by consumers.

3) *Specification and Standards issues:*

Governmental policies and certifications are to be enacted to establish and uphold the minimum acceptable quality standards, operational standards, and minimum requirement specifications to be met by SFM manufacturers before final approval is obtained towards mass production to the public. Matuschek et al. [2] affirmed the need for a well-defined recommendation for the use of smart face masks. An example is ensuring that the techno-driven protective clothing does not pose safety, privacy and other health burdens to the wearers regardless of their age or existing comorbidities.

C. Future Research Directions

This study has some limitations. First, the review of SFMs conducted is limited to those published and indexed in the SCOPUS database. Second, most of the SFMs discussed in this paper are still in their prototype stage and emerging, so there is possibility that some changes and improvements may be made to the SFMs over time that may extend the current scope reported in this paper. A lot of future research opportunities are evident with the emergence of smart face masks. In the meantime, there may be a need to conduct a global spatiotemporal readiness assessment of the adoption and use of SFM by the public. This attempt is necessary to understand public opinion regarding certain controversial issues surrounding its use. In preparation for the next-generation protective smart face mask, future research can investigate how smart sensing can accurately discriminate particles and aerosols of the different air-borne diseases for easy and accurate detection and disease-specific customization of SFMs from the design stage. The emergence of connected masks network is also becoming imminent. This may necessitate the need for the development of dedicated cybersecurity algorithms, security protocols and frameworks to build resilience towards secure SFM networks and clusters. In addition, developing forensic readiness frameworks [15] with SFM use-cases may also be necessary for gathering digital forensic evidences for future forensic investigation in case of a security or privacy breach in connected masks. Furthermore, how mobile computing and smart face mask technologies can collectively provision a more sustainable, scalable and efficient means to health services and data management is also worthy of investigation.

VI. CONCLUSION

In the light of the deadly Covid-19 disease pandemic, face masks were introduced to curtail its widespread. Some emerging evidence have established that the proper use of quality face masks could help to mitigate the spread of the viral disease [11]. However, the use of traditional face masks in pandemic situations comes with a number of challenges including but not limited to high susceptibility of infection or re-infection of the wearer, air flow obstructions, cultural misunderstanding and stigmatization, limited social interactions and communications, quality control and cost issues. Recently, innovation in face mask design has taken on a new dimension with the emergence of smart face masks. Smart face mask is a multisensor device with the capability to intelligently provide multiple dedicated health care services beyond being a protective face cover. In this paper, the main purpose is to provide a concise systematic review of the features, architecture and design, opportunities, challenges, and future research directions of the emerging smart face masks.

From our findings, common features of the emerging SFMs include reusability, self-power generation ability, energy awareness and aerosol filtration efficiency. In addition, extended capabilities of SFMs include but are not limited to the automatic detection of microbes and aerosols, remote health-metrics sensing and monitoring, disease screening and diagnosis, air quality sensing, mask usage time sensing, wireless CO2 monitoring, mask fitness sensing, head and body motion sensing. These extended capabilities have eliminated the challenges of the traditional face masks. Furthermore, SFM can also serve as a tool for messaging and calling to aid effective communication among people in pandemic situations. Similarly, we discover that most of the SFMs have mobile application interface support for the end-users of the smart face masks. A number of challenges identified with the use of SFM in literature include limited public acceptance owing to possibility of public surveillance, privacy and security concerns, lack of government policy, regulations and standards that define and establish quality control and ethical manner for the collection, storage and the use of SFM data. Therefore, it may be interesting for the stakeholders to understand how the use of SFMs affects the people socially beyond its function as a wearable device to curb Covid-19 transmission. Understanding the end-users' experience and opinions about how the use of SFM can be made more effective is also important for it to gain wider public acceptability. In addition, being wearable, issues relating to appearance, weight and level of comfort of SFMs should be taken into consideration to aid user acceptance. Finally, it would be useful to extend and integrate SFM with multiple classes of antimicrobial agents for early detection and prompt effective management of Covid-19 disease pandemic and other communicable diseases' outbreak in the future with wide public acceptance. The high tendency that smart face masks could participate in an Internet-of-Things network also necessitates the need for cybersecurity measures to be developed or put in place to secure its communication and data.

ACKNOWLEDGMENT

We thank all who in one way or another contributed to the completion of this paper. First, I give thanks to God for protection and ability to do work.
